Debugging large-scale applications is challenging

"On average, software developers spend 50% of their programming time finding and fixing bugs."[1]

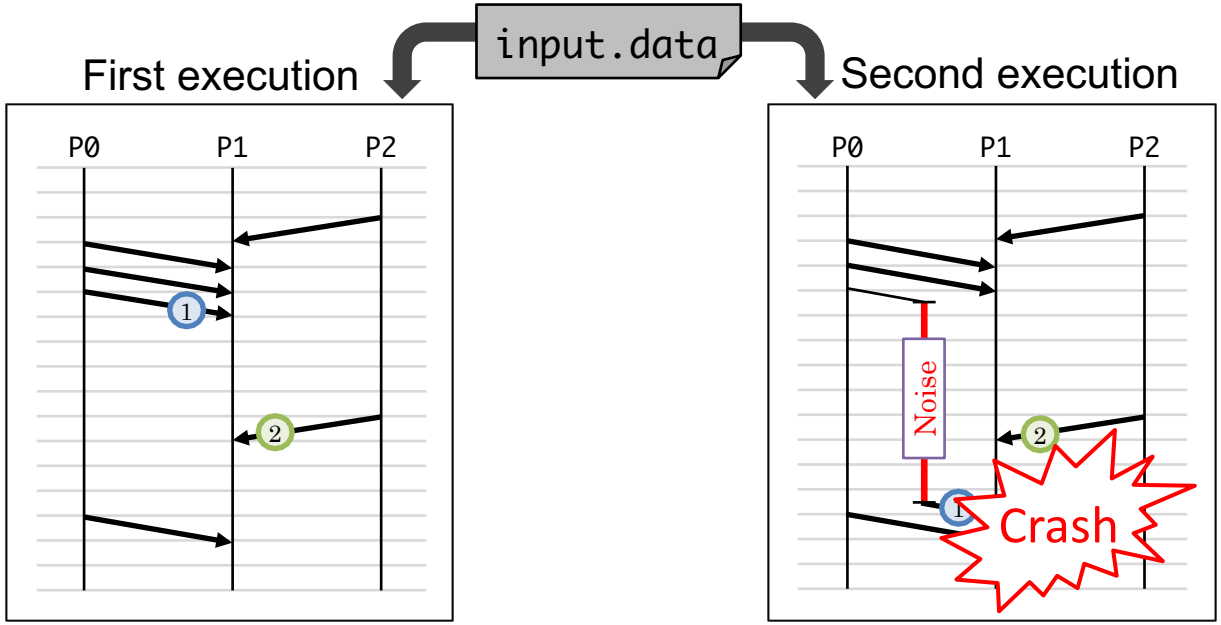
[1] Source: http://www.prweb.com/releases/2013/1/prweb10298185.htm, CAMBRIDGE, UK (PRWEB) JANUARY 08, 2013

In HPC, applications run in parallel
which makes debugging particularly challenging

“MPI non-determinism” makes debugging applications even more complicated

- MPI supports wildcard receives
  - MPI processes can wait messages from any MPI processes
- Message receive orders can change across executions
  - Due to non-deterministic system noise (e.g. Network, OS jitter)

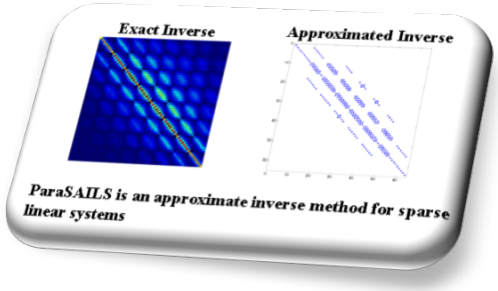
➔ MPI non-deterministic application which correctly ran in first execution can crash in the second execution even with the same input



Real-world non-deterministic bugs in Diablo/Hypre 2.10.1*

- MPI non-deterministic bugs cost computational scientists substantial amounts of time and efforts

Diablo/Hypre 2.10.1



The scientists

- It hung only once every 50 runs after a few hours
- The scientists spent 2 months in the period of 18 months, and then gave up on debugging it

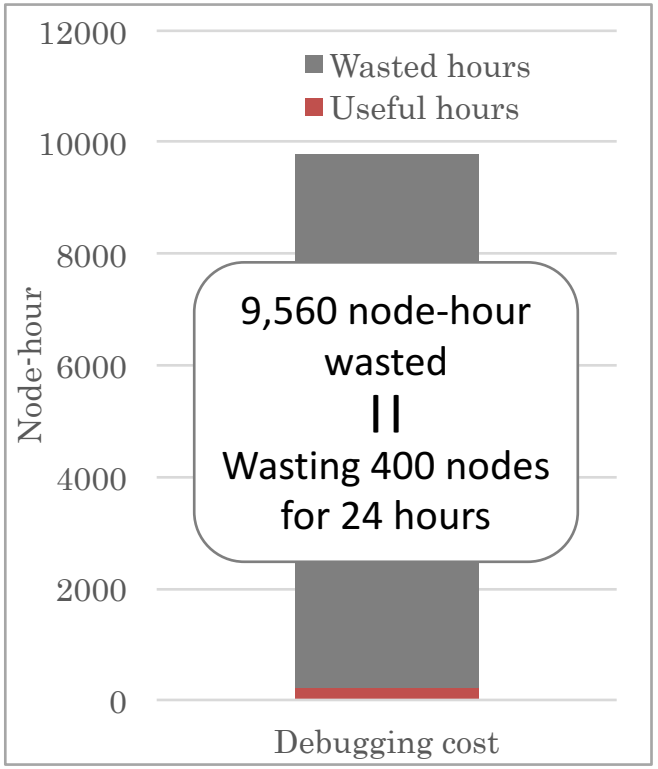
Our debugging team

- We found that the cause is due to a ”Unintended message matching” by misused MPI tag (message race bug)
- We spent 2 weeks in the period of 3 months to fix the bug

* Hypre is an MPI-based library for solving large, sparse linear systems of equations on massively parallel computers

Observing a non-deterministic bug is costly

- Due to such non-determinism, we needed to submit a bunch of debug jobs to observe the bug
  - The bug did not manifest in 98% of jobs
  - Wasted 9,560 node-hour
- Rarely-occurring message race bugs waste both scientists' productivity and machine resources (thereby affect also other users)



A tool to frequently and quickly expose message race bugs is invaluable

NINJA

- NINJA: Noise Injection Agent
  - Frequent manifestation: Injects network noise in order to frequently and quickly expose message race bugs
  - High portably: NINJA is developed in MPI profiling layer (PMPI)

- Experimental results
  - NINJA consistently manifests the Hypre 2.10.1 message race bug which does not manifest itself without NINJA

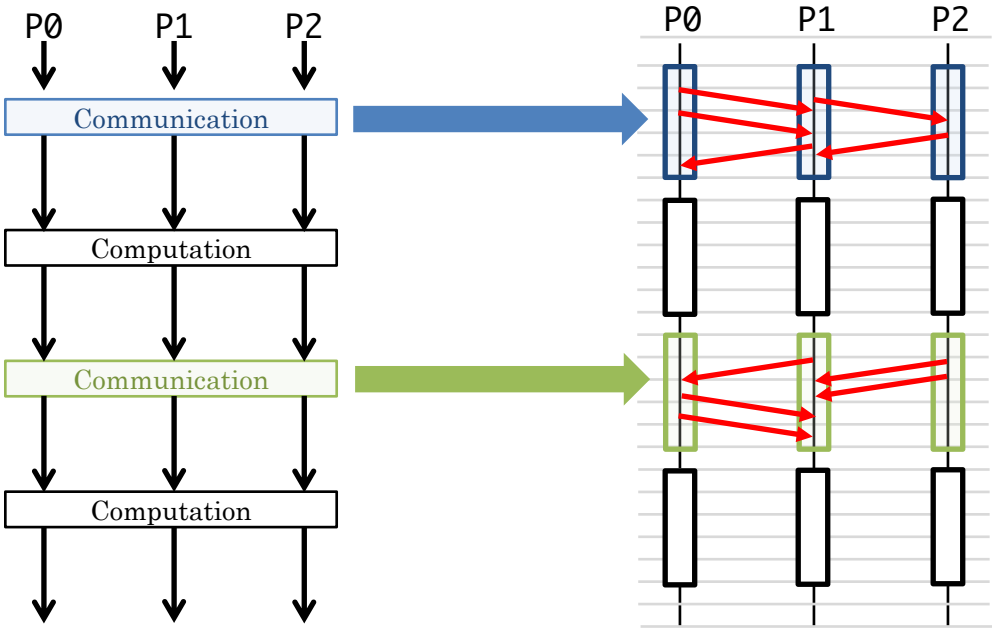
Outline

- Introduction
- Message race bugs
- NINJA: Noise Injection Agent
- Evaluation
- Conclusion

Data-parallel model (or SPMD)

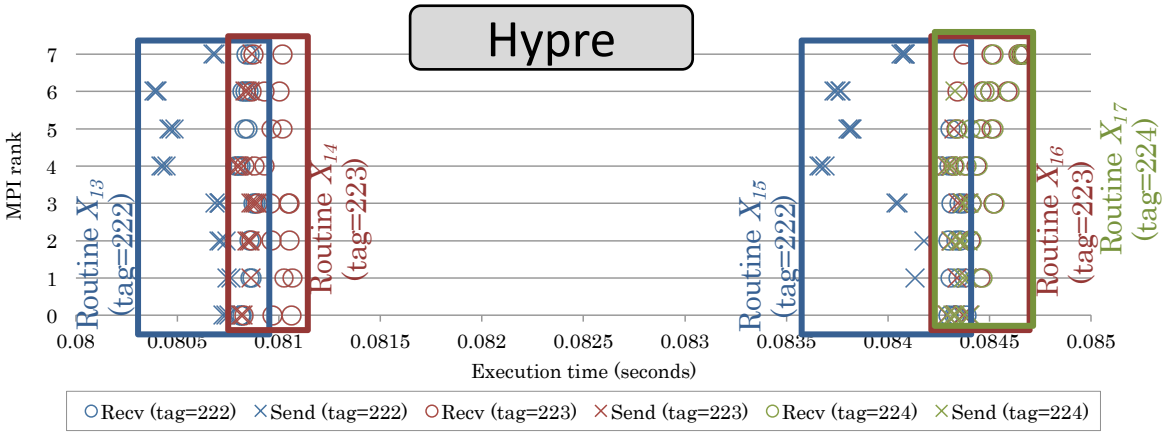
- In HPC, many applications are written based on a data-parallel model (or SPMD)
  - Easy to scale out the application by simply dividing a problem across processes
- In SPMD, each process calls the same series of routines in the same order
- So messages sent in a communication routine are all received within the same communication routine

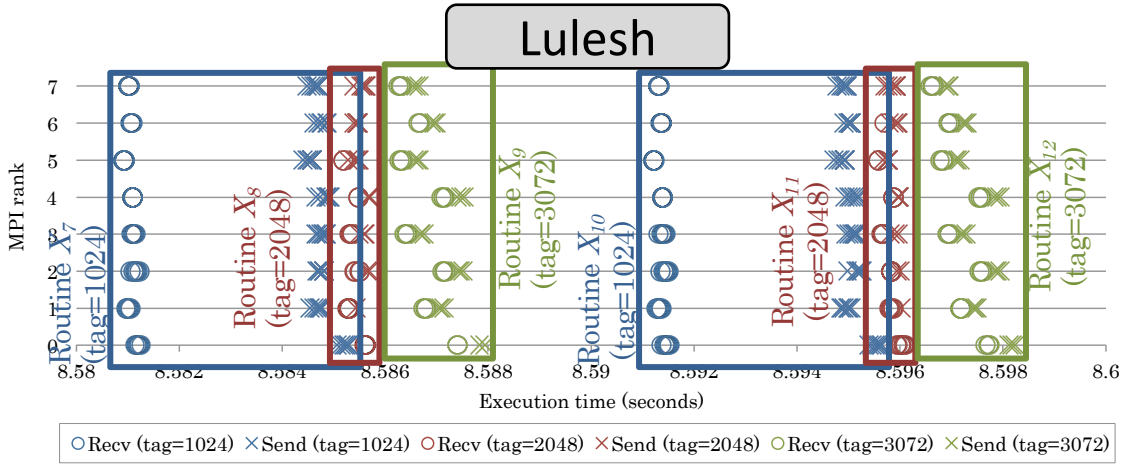
  ➔ "self-contained" communication routine (or communication routine)



Plots of Send and Receive time stamps

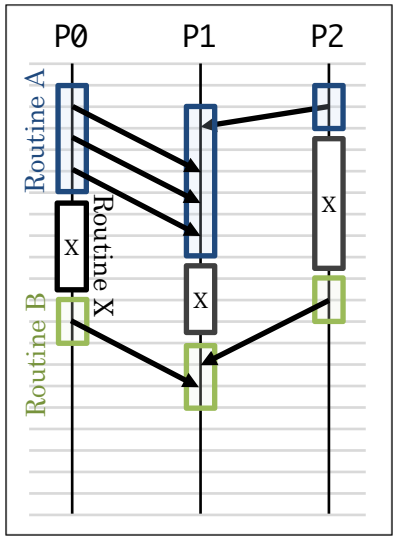
- HPC apps call a series of self-contained communication routines step-by-step
  - Each colored box illustrates a self-contained routine



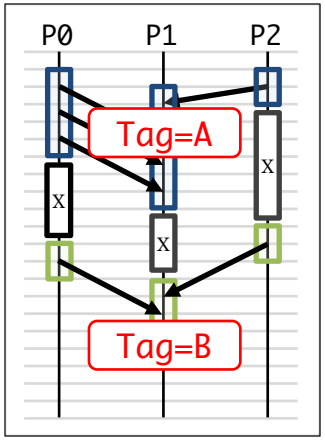


Avoiding message races

- To make communication routines "self-contained", common approaches in MPI are:
  - Use of different tags/communicators
  - Calling synchronization (e.g. MPI_Barrier)

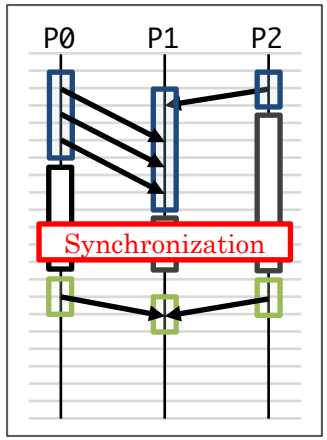


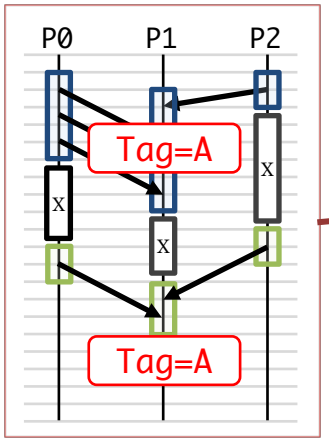
Different tags/communicators



OR

Synchronization

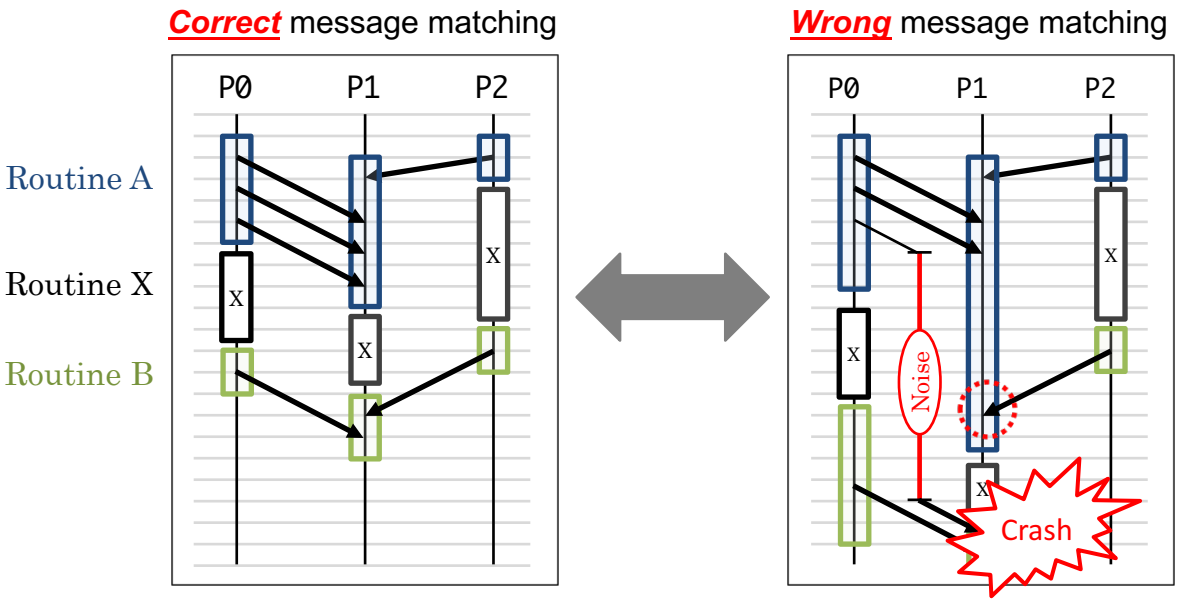




If these conditions are violated, applications potentially embrace message race bugs

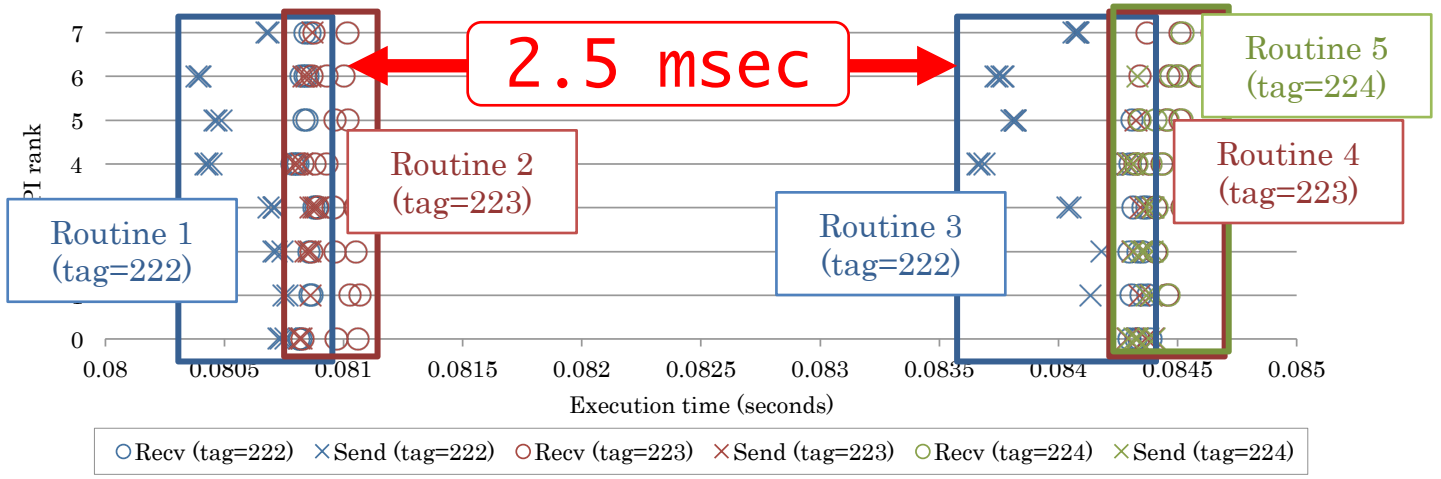
Message race bugs are non-deterministic

- Manifestations of message race bugs depend on system noise
  - Occurrences and amounts of system noise are non-deterministic
- Message race bugs rarely manifest, E.g., when
  1. System noise level is low
  2. Unsafe routines (Routine A and Routine B) are separated by interleaving routines (Routine X)



Case study: Diablo/Hypre 2.10.1

- The message race bug in Hypre manifest when a message sent in Routine 3 is received in Routine 1
  - Routine 1 & 3: same MPI tag without synchronization

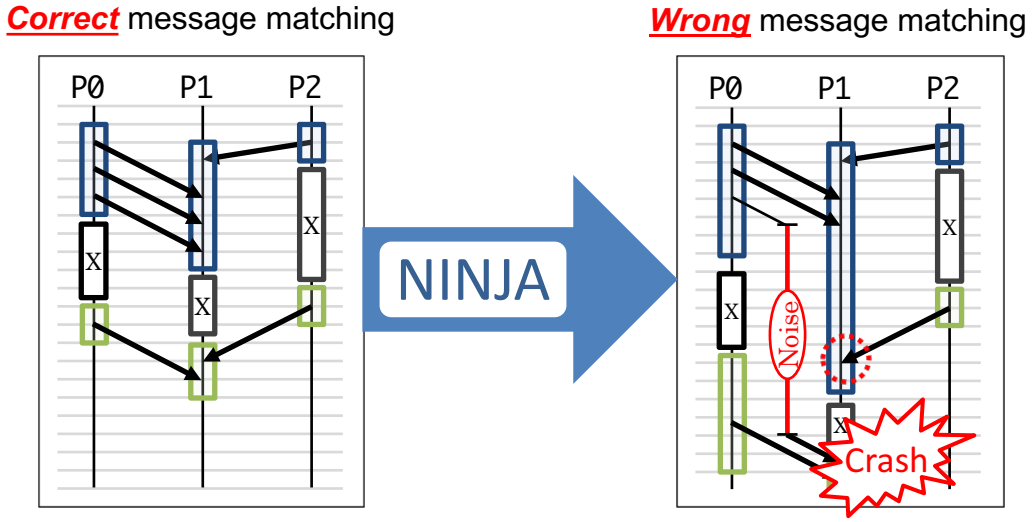


However, Routine 1 and 3 are significantly separated by 2.5 msec, the message race bug rarely manifest

We need a tool to frequently expose subtle message race bugs

NINJA: Noise Injection Agent Tool

- NINJA emulates noisy environments to expose subtle message race bugs

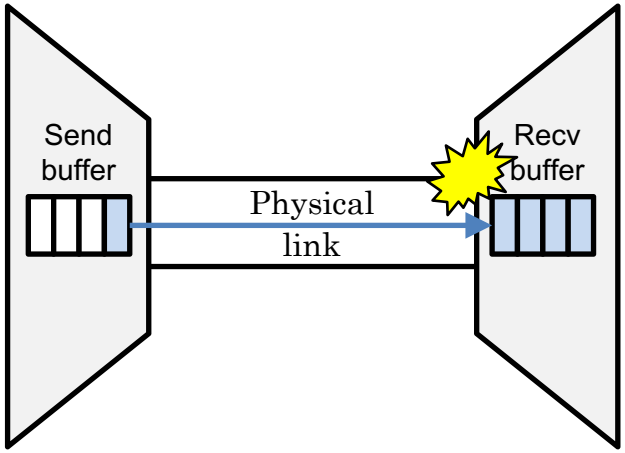


- Two noise injection modes
  - System-centric mode : NINJA emulates congested network to induce message races
  - Application-centric mode : NINJA analyzes application's communication pattern, and inject a sufficient amount of noise to make two unsafe routines overlapped

System-centric mode emulates noisy network

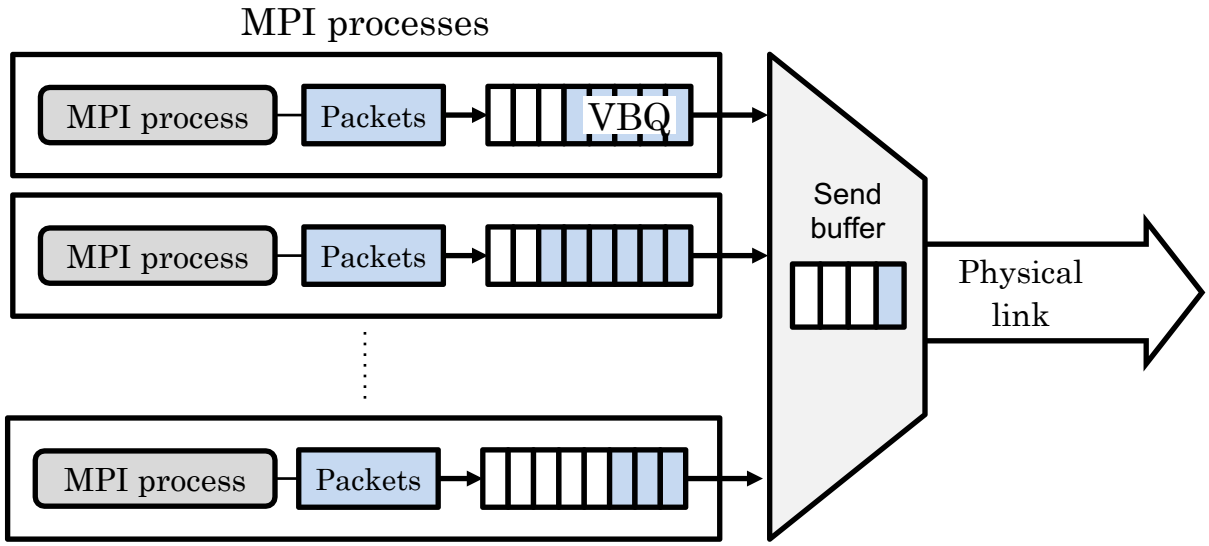
- System-centric mode emulates noisy network based on a conventional “flow control” in interconnects

- Conventional flow control
  - When sending a message, the message is divided into packets and queued into a send buffer
  - The packets are transmitted from a send buffer to a receive buffer
  - If the receive buffer does not have enough space, flow control engine suspends packet transmission until enough buffer space is freed up



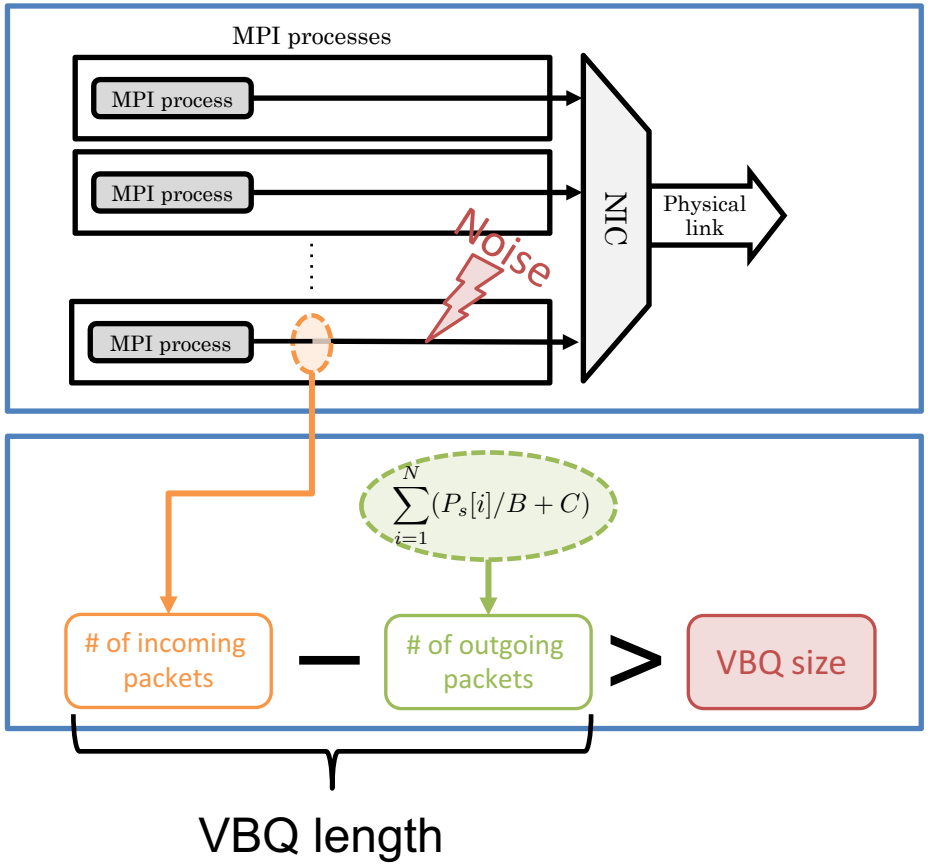
NINJA implements flow control at process-level

- NINJA's flow control
  - Each process manages virtual buffer queue (VBQ)
  - If VBQ does not have enough space, NINJA delays sending the MPI message until enough buffer space is freed up



How NINJA triggers noise injection ?

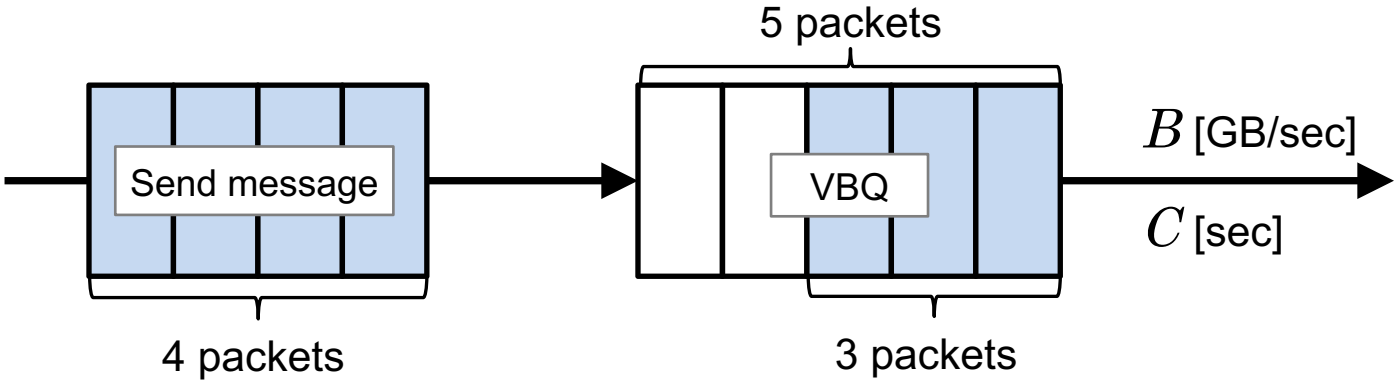
- NINJA system-centric mode
  - Monitor # of incoming packets
  - Compute # of outgoing packets by using a model based on network bandwidth and latency
  - Estimate VBQ length
  - If VBQ length exceeds the VBQ size, then NINJA injects noise to the message
- NINJA logically estimate VBQ length, so does not physically buffer messages by copying



How much amount of noise is injected ?

- NINJA delay a message send until enough VBQ space is freed up
- Example
  - VBQ size: 5 packets
  - # of packets in VBQ: 3 packets
  - The incoming message: 4 packets

  ➔ NINJA delays this message by the time to transmit 2 packets



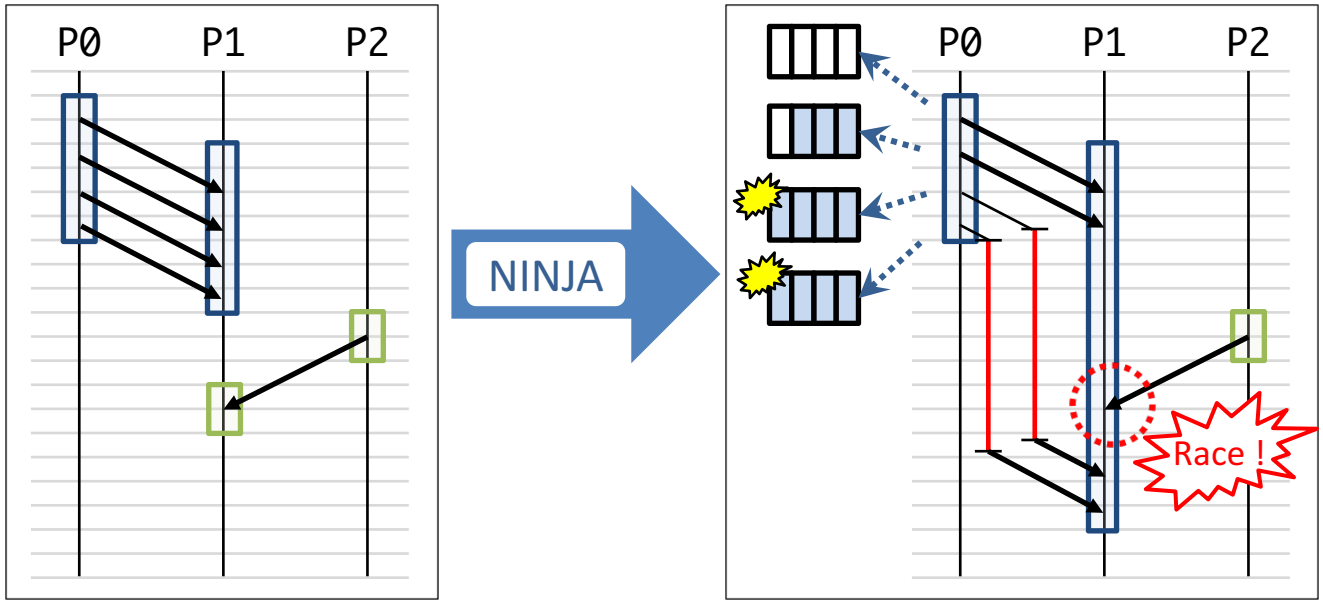
$Packet\ size = 2$ [KB]
$B = 3.14$ [GB/sec]
$C = 0.25$ [µsec]

$$\left(\frac{2\ [\mathrm{KB}]}{3.14\ [\mathrm{GB/sec}]} + 0.25\ [\mu\mathrm{sec}]\right) \times 2\ packets = 1.27\ [\mathrm{msec}]$$

Noise amount

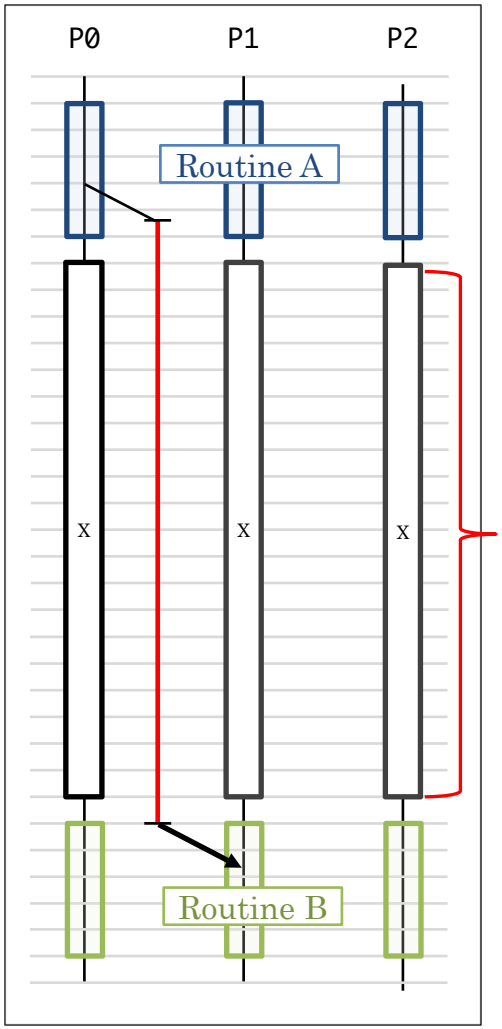
System-centric mode induces message races

- Earlier messages are not delayed in a routine (since buffer space is left) while later messages are delayed in the same routine
- NINJA extends an unsafe routine so that we can overlap one unsafe communication routine with the next communication routine, thereby, induce message races



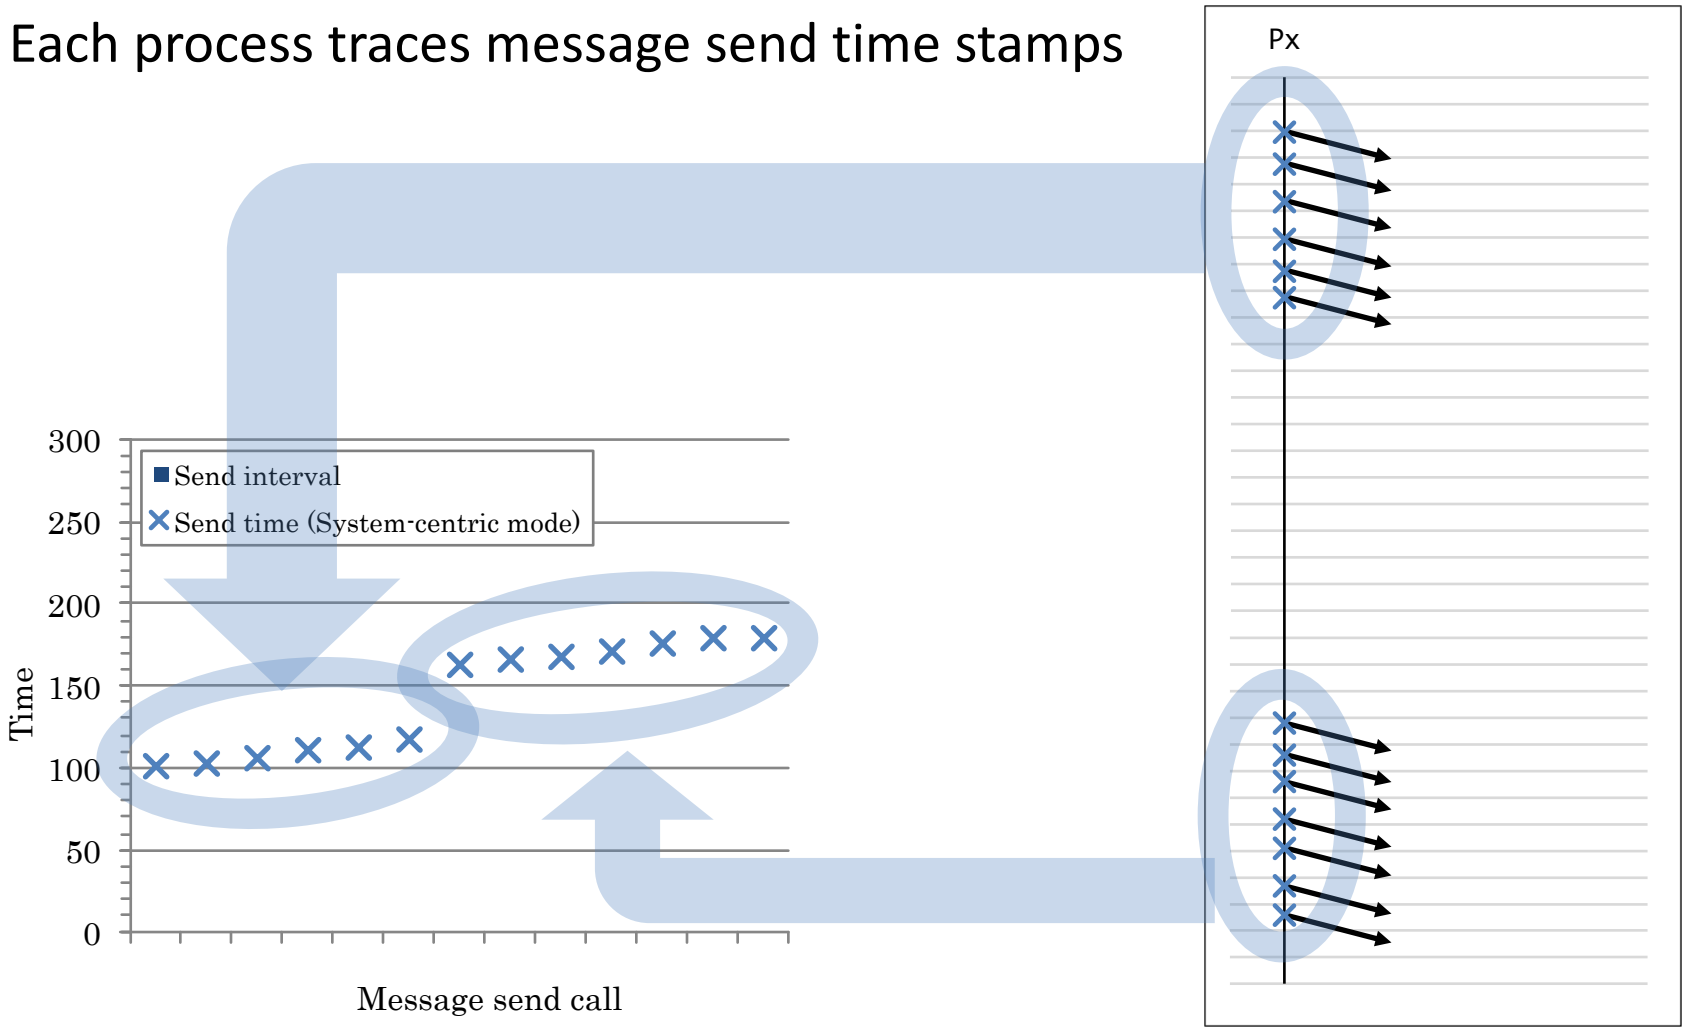
Application-centric mode

- Problem in system-centric mode
  - If unsafe routines (i.e. Routine A and B) are significantly separated, system-centric noise amount is not adequate
- Application-centric mode
  - NINJA analyzes communication patterns during system-centric mode
  - Then, NINJA injects an adequate amount of noise to enforce message races



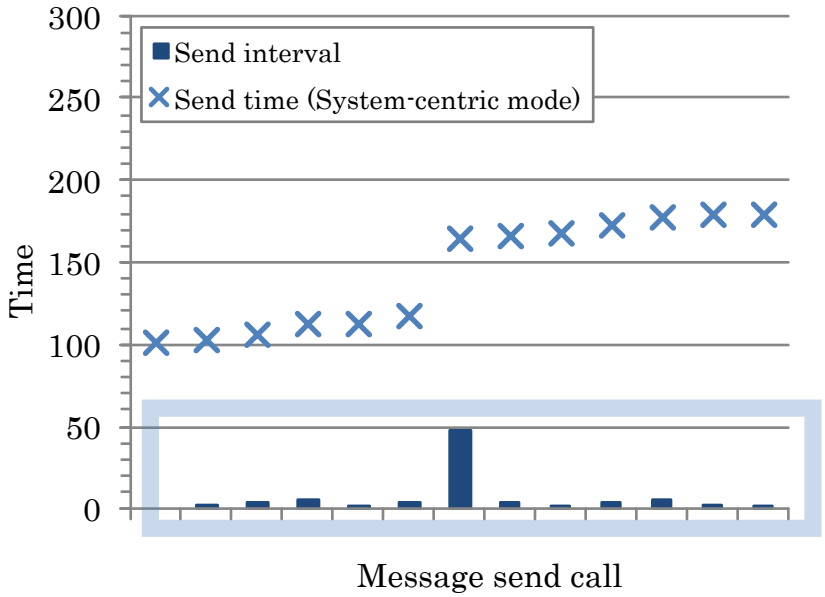
Application-centric mode

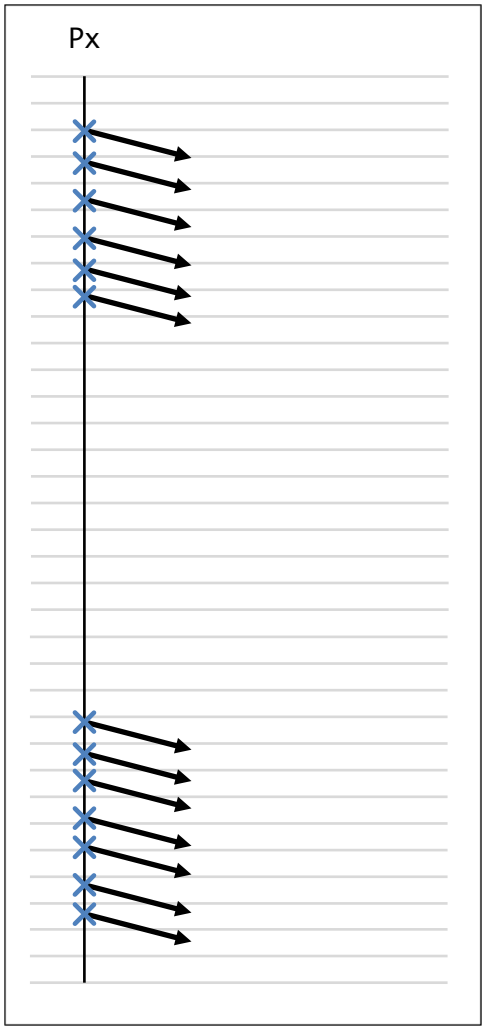
1. Each process traces message send time stamps



Application-centric mode

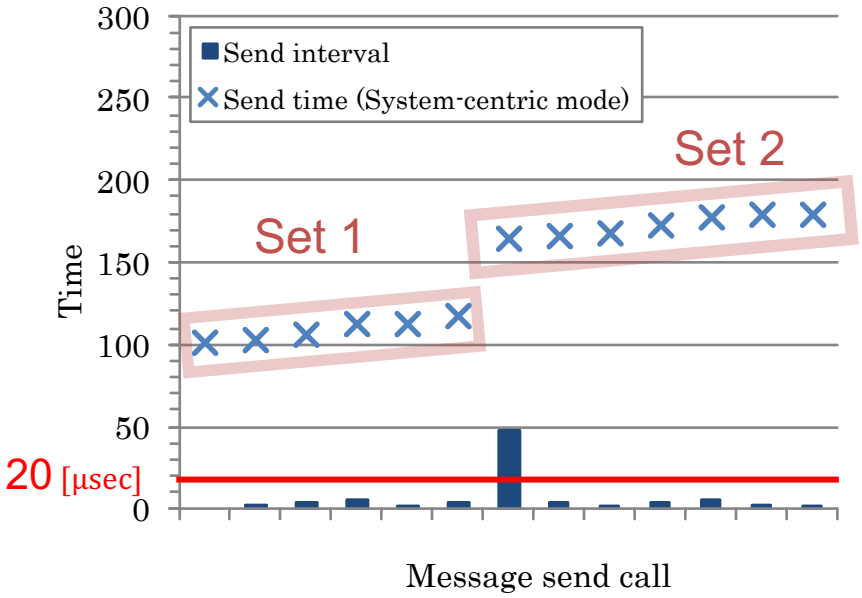
2. Compute message send intervals based on the time stamps

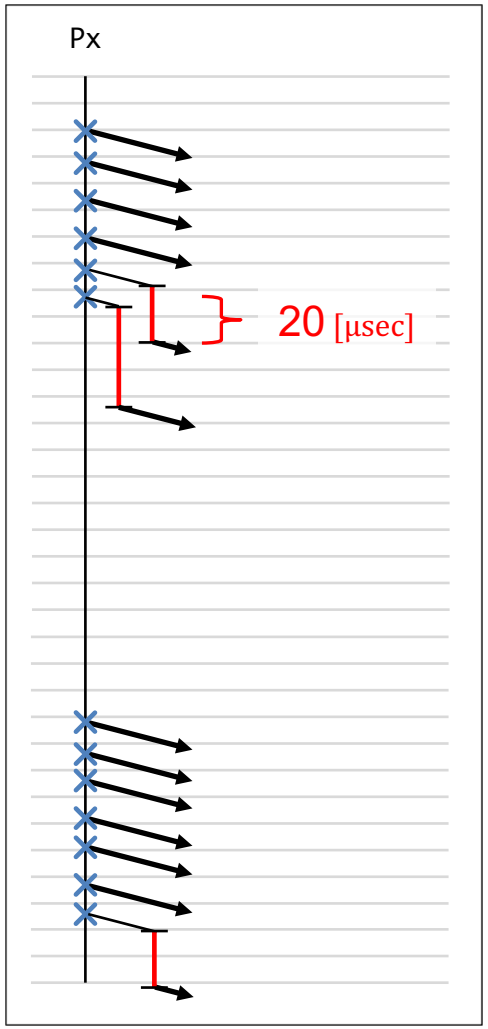




Application-centric mode

3. Detect separated unsafe routines
   - If an interval is more than system-centric noise amount, NINJA regards the routines as separated unsafe routines
   - Example
     - System-centric noise amount: 20 µsec
     - NINJA regards Set 1 and 2 as separated unsafe routines more than system-centric noise amount



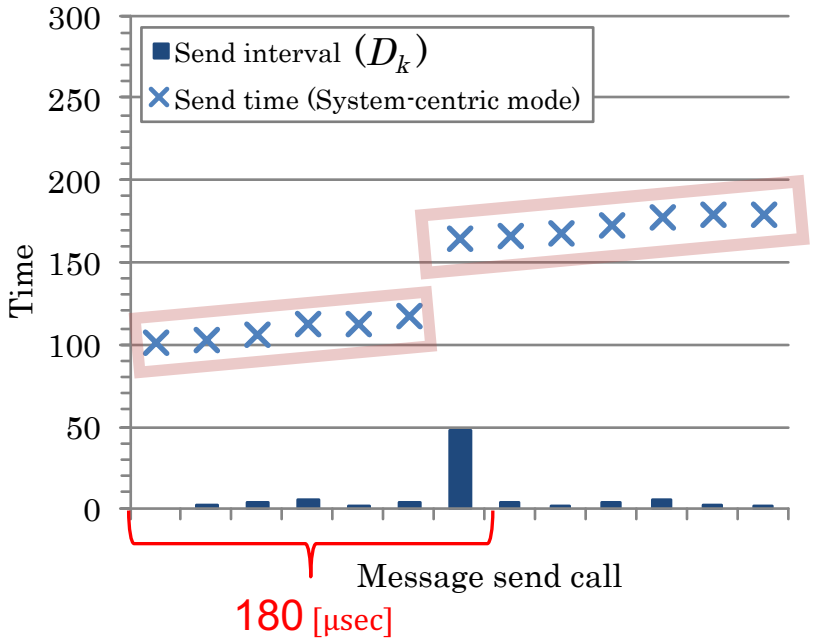


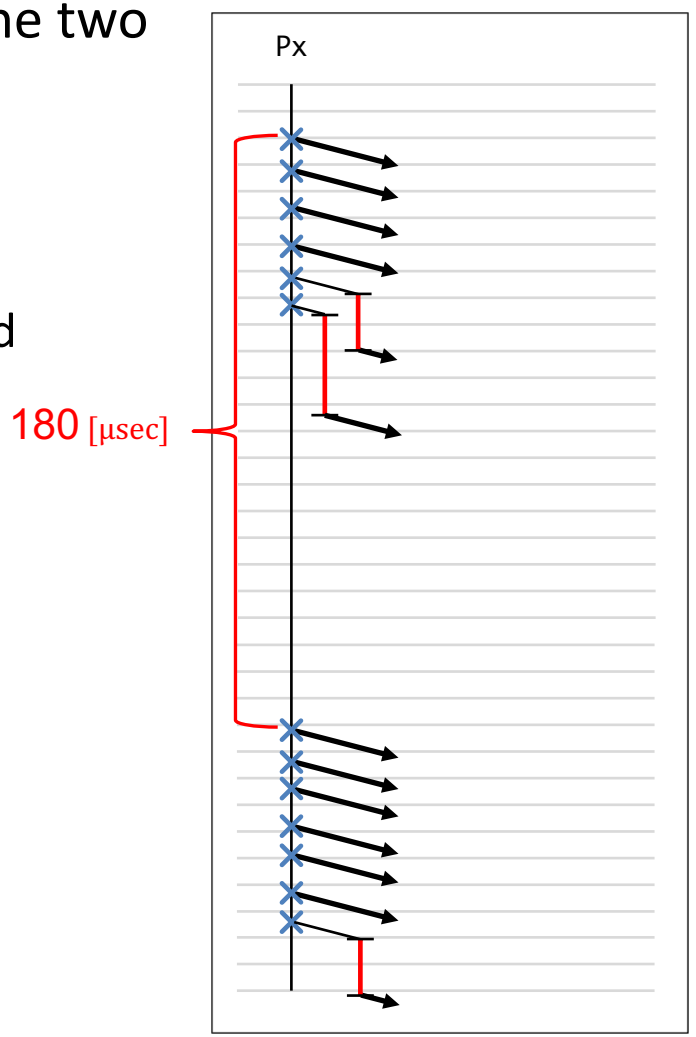
Application-centric mode

4. Compute this separated interval between the two routines

— Sum of intervals: $\sum_{k=m_i}^{m_{i+1}-1} D_k$

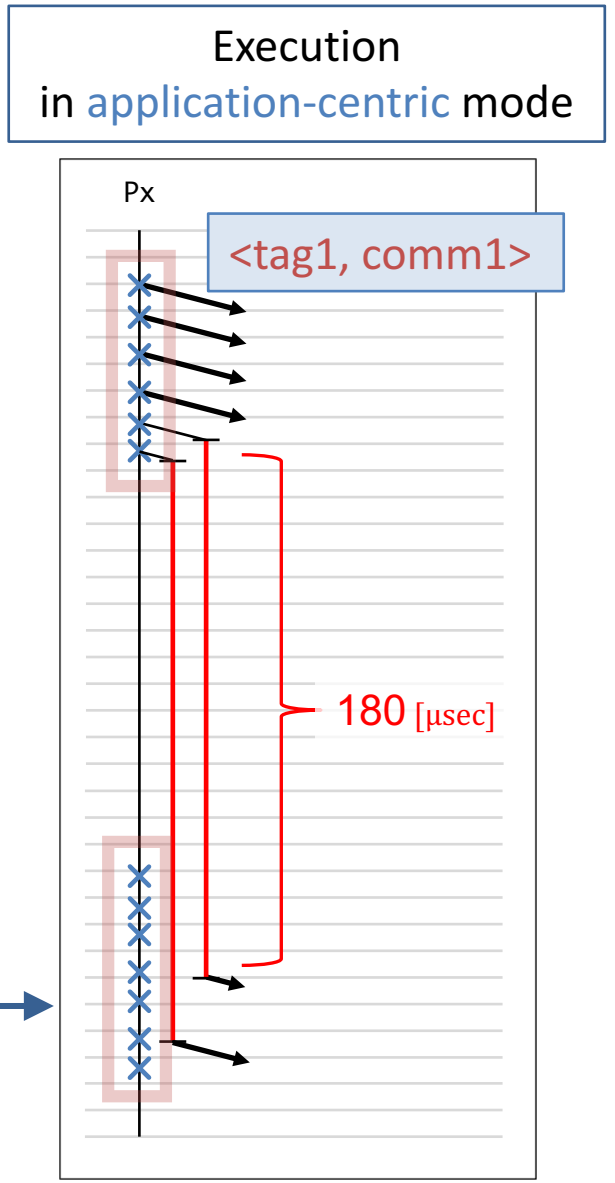
— Updates max of this separated interval every iterations for every detected pairs of separated routines





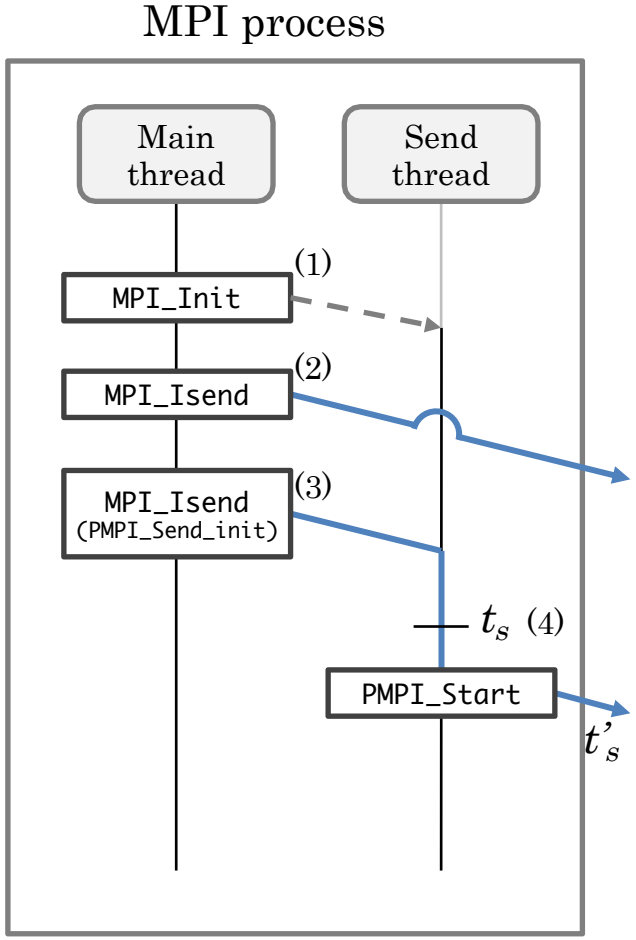
Application-centric mode

- At the end of system-centric mode, each process writes this analysis file
- Application-centric mode read this file and inject noise according this analysis
  - i.e. System-centric mode with auto-tuned noise amount



Implementation

- We implement the noise injection schemes by using PMPI profiling interface
- To inject network noise, we use a send-dedicated thread, one per MPI process
  - (1) MPI Init,
    - Each MPI process spawns this send-dedicated thread
  - (2) MPI_Isend for non-delayed messages
    - Calls PMPI_Isend
  - (3) MPI_Isend for delayed messages
    - The main thread calls PMPI_Send_init, computes the amount of delay, and set delayed send time
  - (4) PMPI_Start
    - The send thread periodically check the send time
    - When the scheduled send time comes, the send thread calls PMPI_Start



Evaluation

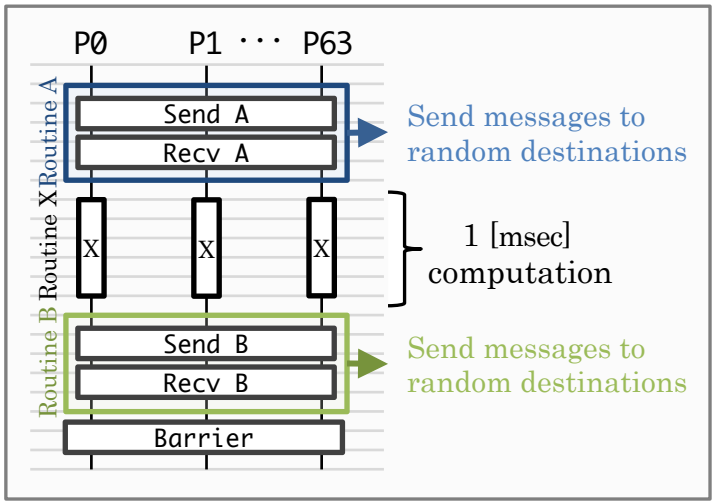
- Cases
  - Two synthetic benchmarks: Case 1 and 2
  - Parasail module in Hypre 2.10.1
    - Computes a sparse approximate inverse pre-conditioner, which is used by Diablo
- Environment
  - MVAPICH-2.1
  - LLNL systems
    - Run 64 processes in 4 nodes

Less noisy system

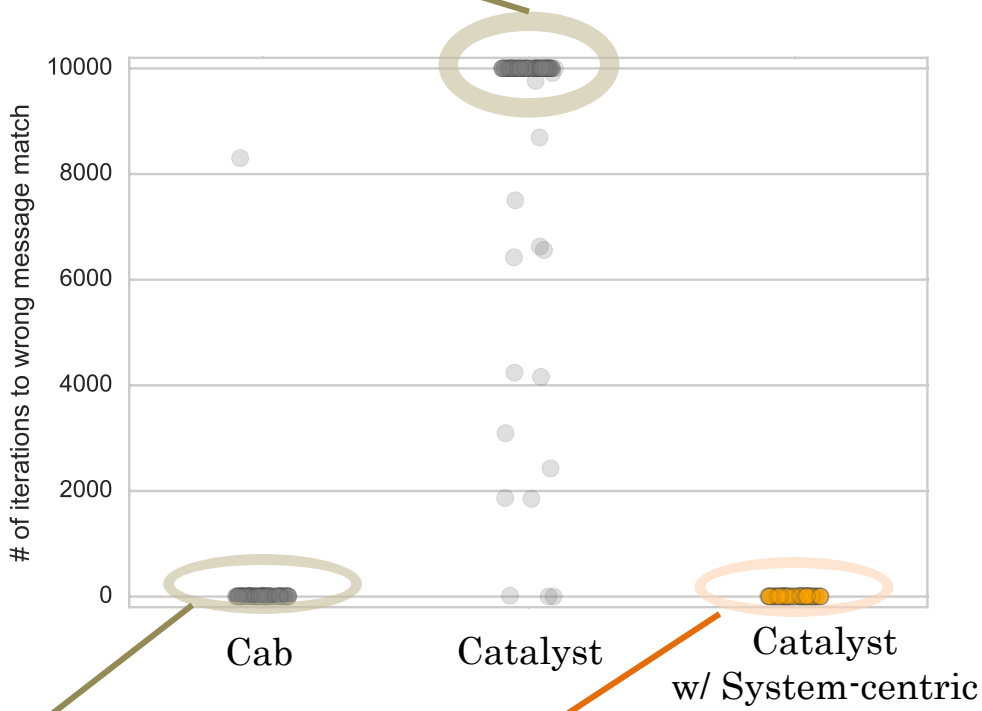
	Cab	Catalyst
Nodes	1,200 batch nodes	304 batch nodes
CPU	2.6 GHz Intel Xeon E5-2670 (16 cores per node)	2.4 GHz Intel Xeon E5-2695 v2 (24 cores per node)
Memory	32 GB	128 GB
HCA	InfiniBand QDR4X (QLogic)	InfiniBand QDR4X (QLogic) x2

- Evaluate the number of loops at which a message race occurs

Case 1: Send-Receive



Max Iterations: 10,000

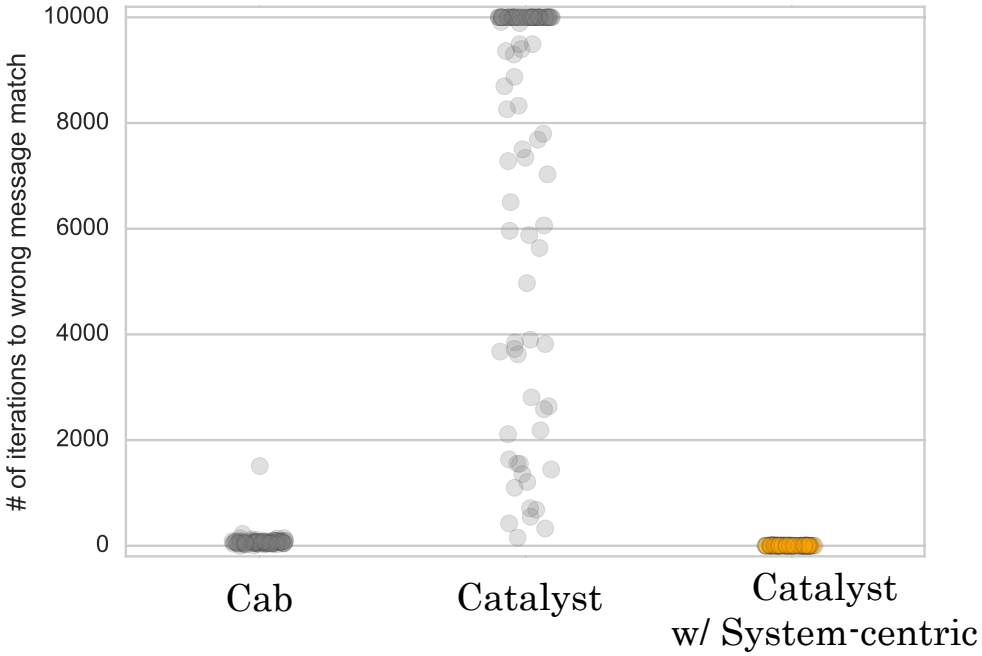


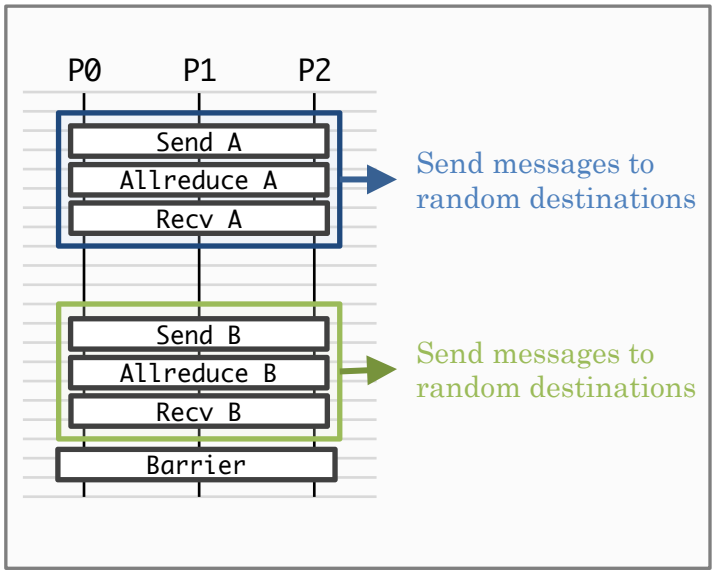
2. In less noise system, this message race rarely manifest

1. In Cab, this message race easily manifest itself without NINJA because Cab is relatively noisy system

3. If we use NINJA in catalyst, we can frequently and immediately manifest message race even in this less noisy system

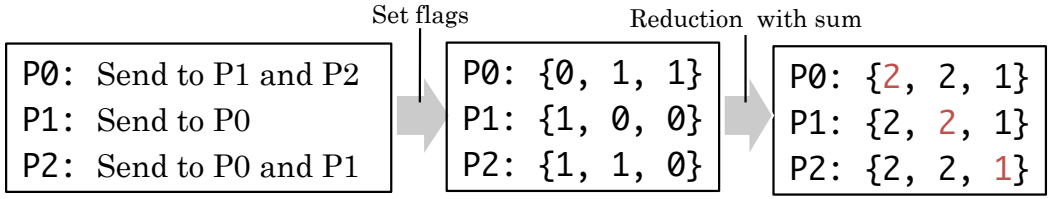
Case 2: Send-AllReduce-Receive





Max Iterations: 10,000

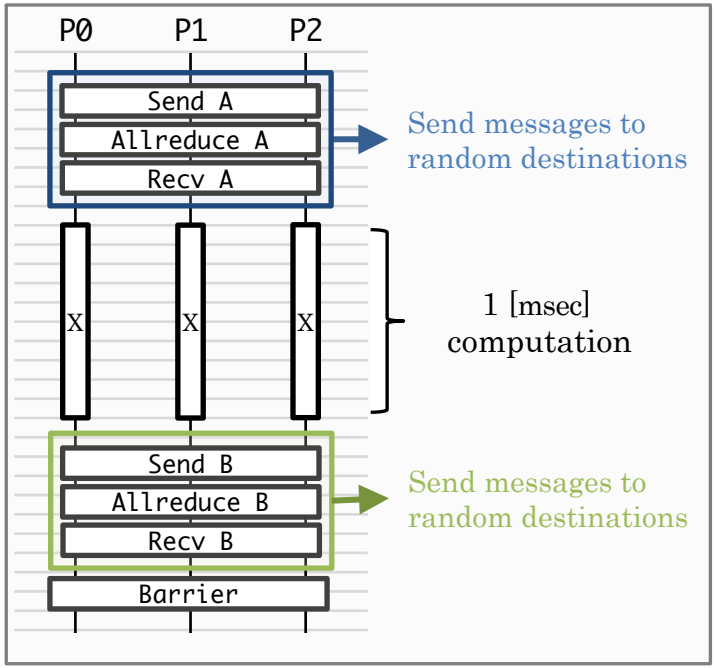
Typical communication patterns
when each MPI rank does not know how many messages arrive



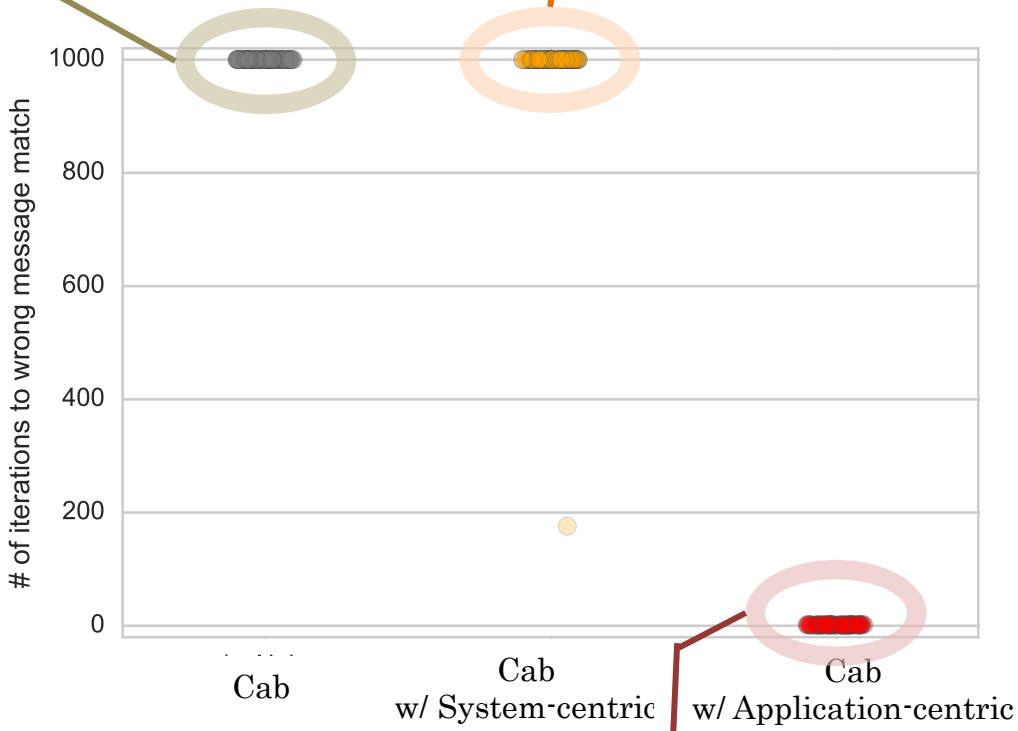
Case 2: Send-Allreduce-Receive with 1 msec interval

1. Message race does not manifest at all even in Cab

2. System-centric noise also cannot manifest the message races because noise amount is too small for these unsafe routine separated by 1 [msec]



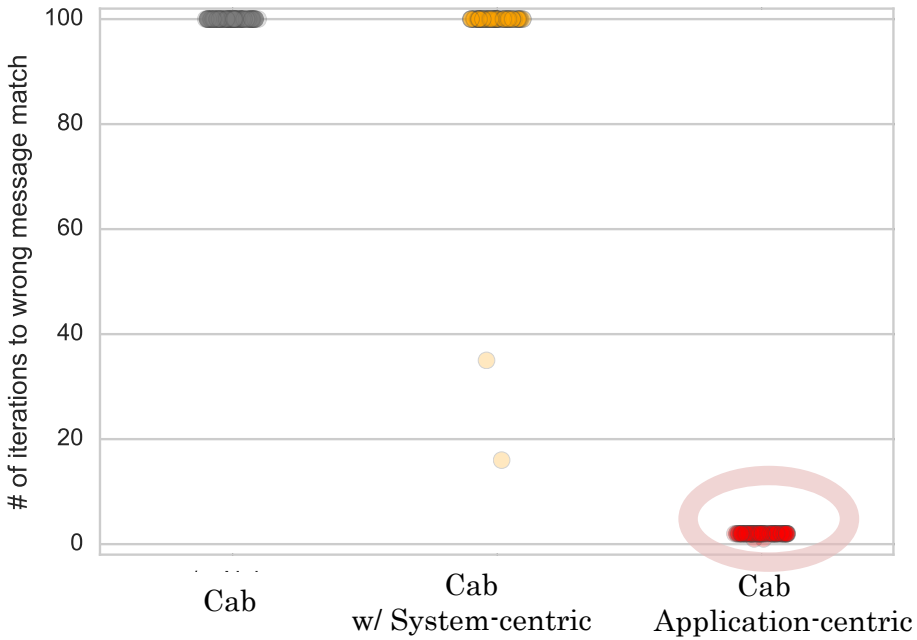
Max Iterations: 1,000

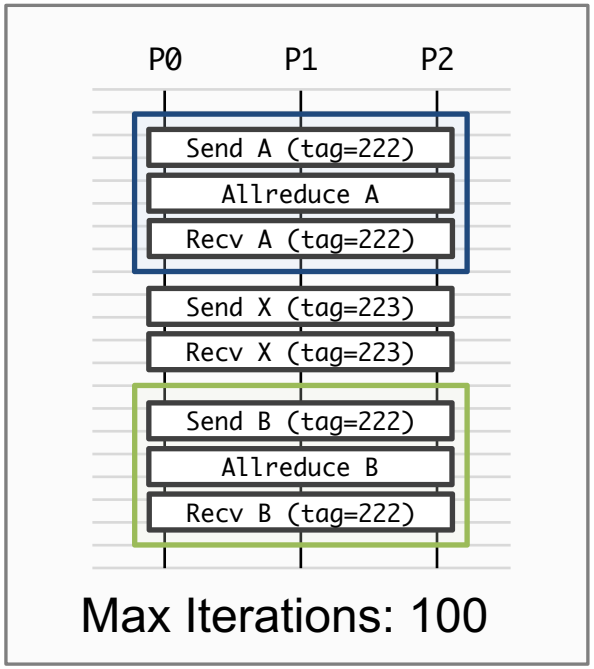


3. Application-centric noise can consistently and immediately manifest message races because this mode analyzes how much unsafe routines are separated and injects adequate amount of noise

Hypre 2.10.1

- NINJA also successfully manifest real message race bugs with application-centric mode

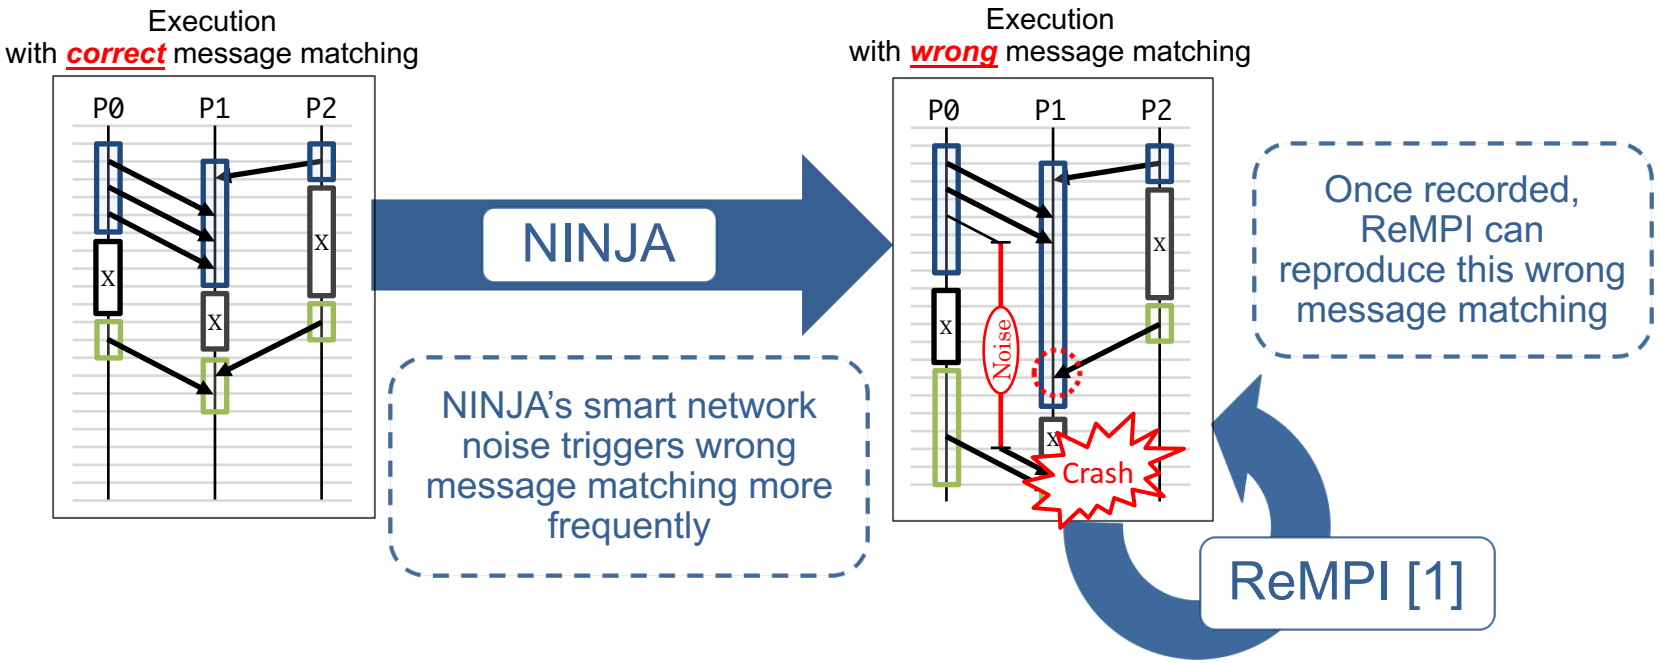




Unsafe communication routines in Hypre 2.10.1

Discussion

- Disadvantage: NINJA cannot reproduce the same message race
  → However, the same message race can be reproduced by using MPI record-and-replay technique



[1] Kento Sato et al. "Clock Delta Compression for Scalable Order-Replay of Non-Deterministic Parallel Applications", SC15

Conclusion

- Debugging large-scale HPC applications are becoming more challenging
- Rarely-occurring message race bugs hamper debugging productivity because they do not frequently manifest
- NINJA can frequently and immediately manifest such message race bugs
- As future work, we will integrate NINJA with ReMPI
  - Currently, NINJA and ReMPI are independent tools

Thanks !

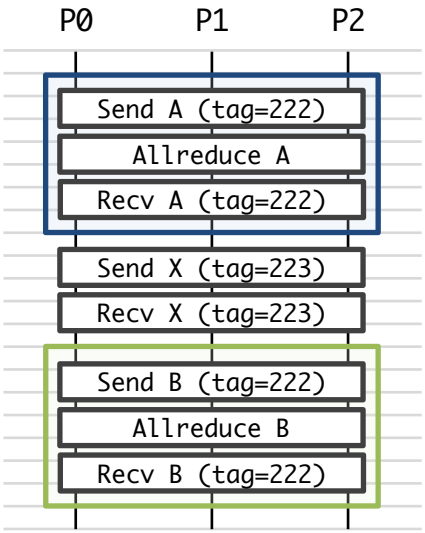
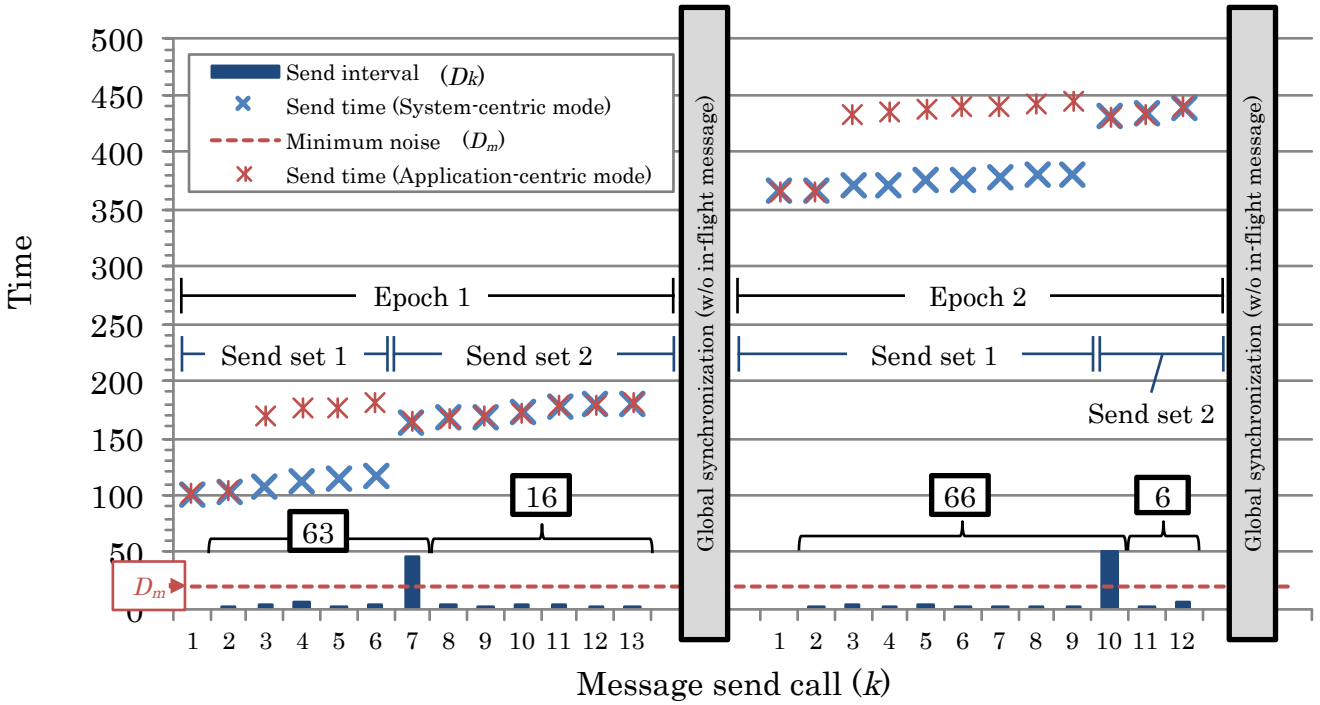
Routine

```
Routine(tag=X) {
  Sends(tag=X); // Send messages (tag=X): S = {s1, s2, …, sn}
  Recvs(tag=X); // Rcve messages (tag=X): R = {r1, r2, …, rn}
  // Set S and R are equal (S = R) in successful run
}
```



```
Routine(tag=222) {
  Sends(tag=222);
  Recvs(tag=222);
}
Routine(tag=223) {
  Sends(tag=223);
  Recvs(tag=223);
}
Routine(tag=222) {
  Sends(tag=222);
  Recvs(tag=222);
}
```

Application-centric mode: Backup



Implementation

- We implemet the noise injection schemes by using PMPI profiling interface
- To inject network noise, we use a send-dedicated thread, one per MPI process

```
10:  int MPI_Isend (…) {
11:    if (is_delayed) {
12:      PMPI_Send_init(…);
13:      /* Enqueue request for Send thread
14:         with timer t_s */
15:    } else {
16:      PMPI_Isend(…);
17:    }
18:  }
 :
30:  int MPI_Wait (…) {
31:    while (!flag) MPI_Test(…);
32:  }
 :
50:  int MPI_Collective (…) {
51:    PMPI_Icollective(…, &reqest);
52:    MPI_Wait(&request, …);
53:  }
```

# of iterations to wrong message match
w/o Noise (Average=884.7)
w/ S-centric noise (Average=922.5)
w/ A-centric noise (Average=48.6)

Noise injection overhead in Hypre 2.10.1

	Random noise
Noise trigger	90, 50, 10% of messages
Noise amount	Iteration time
Target matching ID	All

3. Random noise can manifest message race bug, however overhead is significantly large

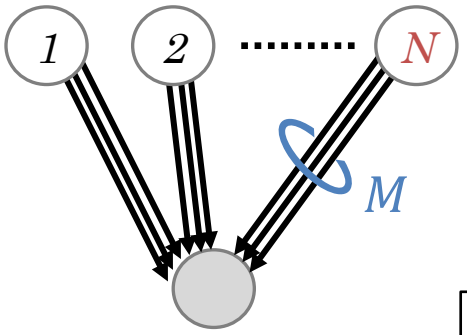
2. Although overhead by application-centric noise is relatively high, this mode can enforce message races

1. System-centric mode simply emulate noise network environments, so the overhead to application is not significant

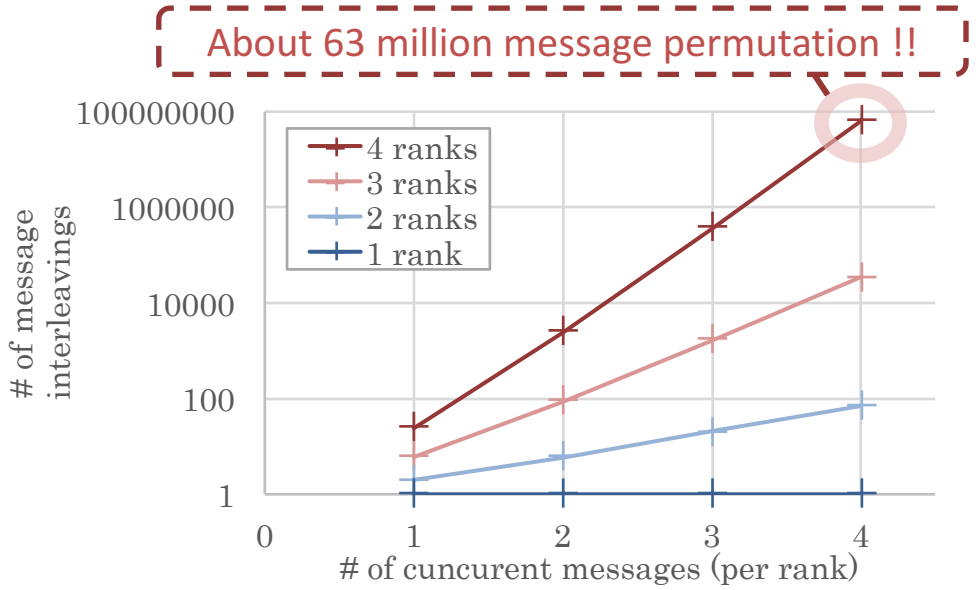
Discussion

- Verification/Testing tool
  - Explores all message interleavings to verify correctness
    - E.g.) Happens-before relationship, Lamport clock
  - Advantage: Verification tools can reproduce message races
  - Disadvantage: Message interleavings pattern are exponentially large
- Exploration space
  - N : The number of ranks; M : The number of concurrent message per rank

➔ Verification/Testing tools need to run for a long time until they hit a bug, and impractical



$$\frac{(N \times M)!}{(M!)^N}$$



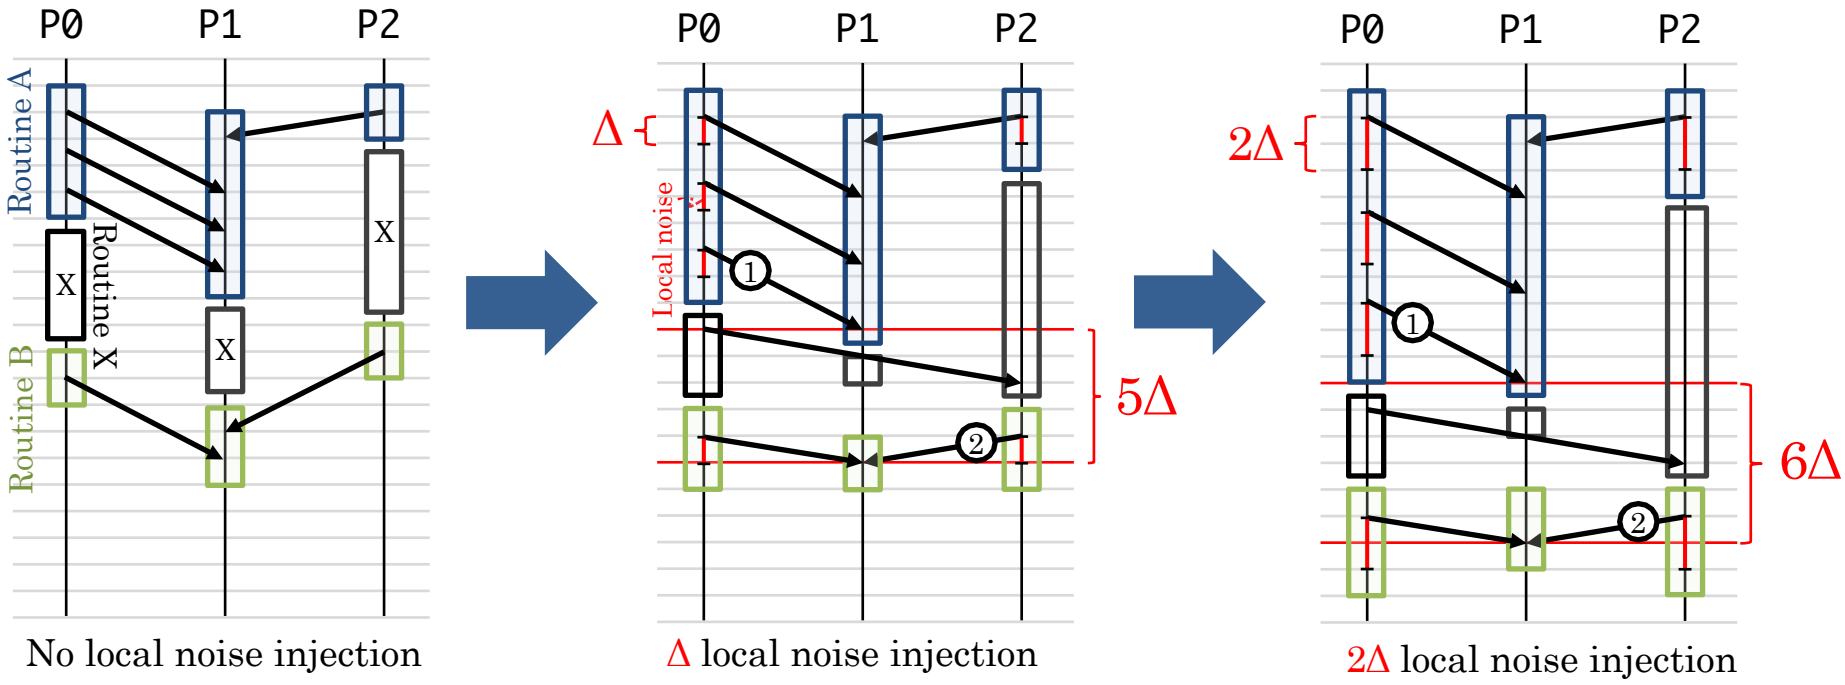
Discussion

- Delay-bounded scheduling
  - Explores possible task/thread schedules until buggy behaviors are hit by delaying MPI processes (→ local noise)

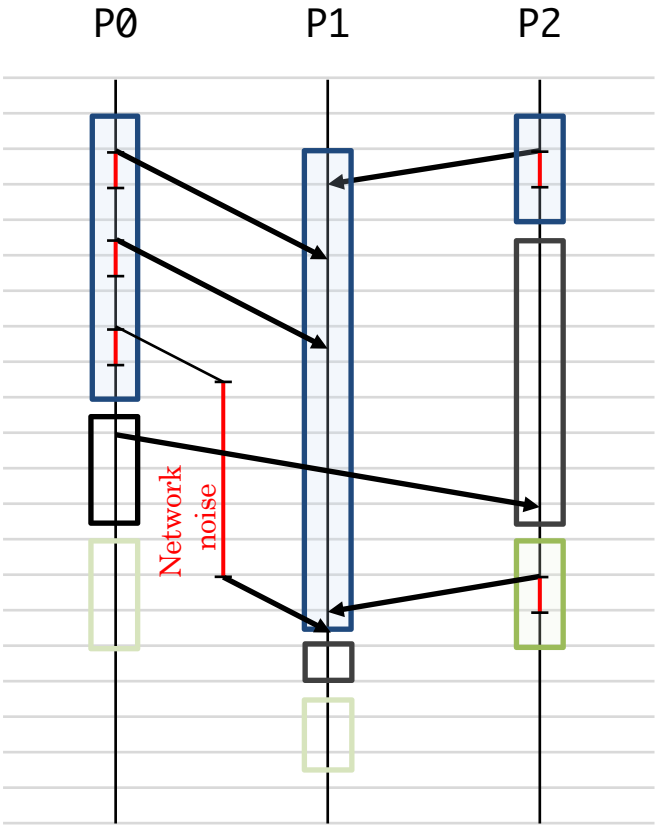
  → Local noise does not always work

Node-local noise is not always effective

- Local noise increase an interval between unsafe routines if Routine X has other interleavings communications
  - Because this noise propagate to other processes
- Separate them more



Network noise can manifest the message race



Case 2

- When unsafe routines are significantly separated, message racace do not manifest
- Even in such case, application-centic mode can manifest messaga race

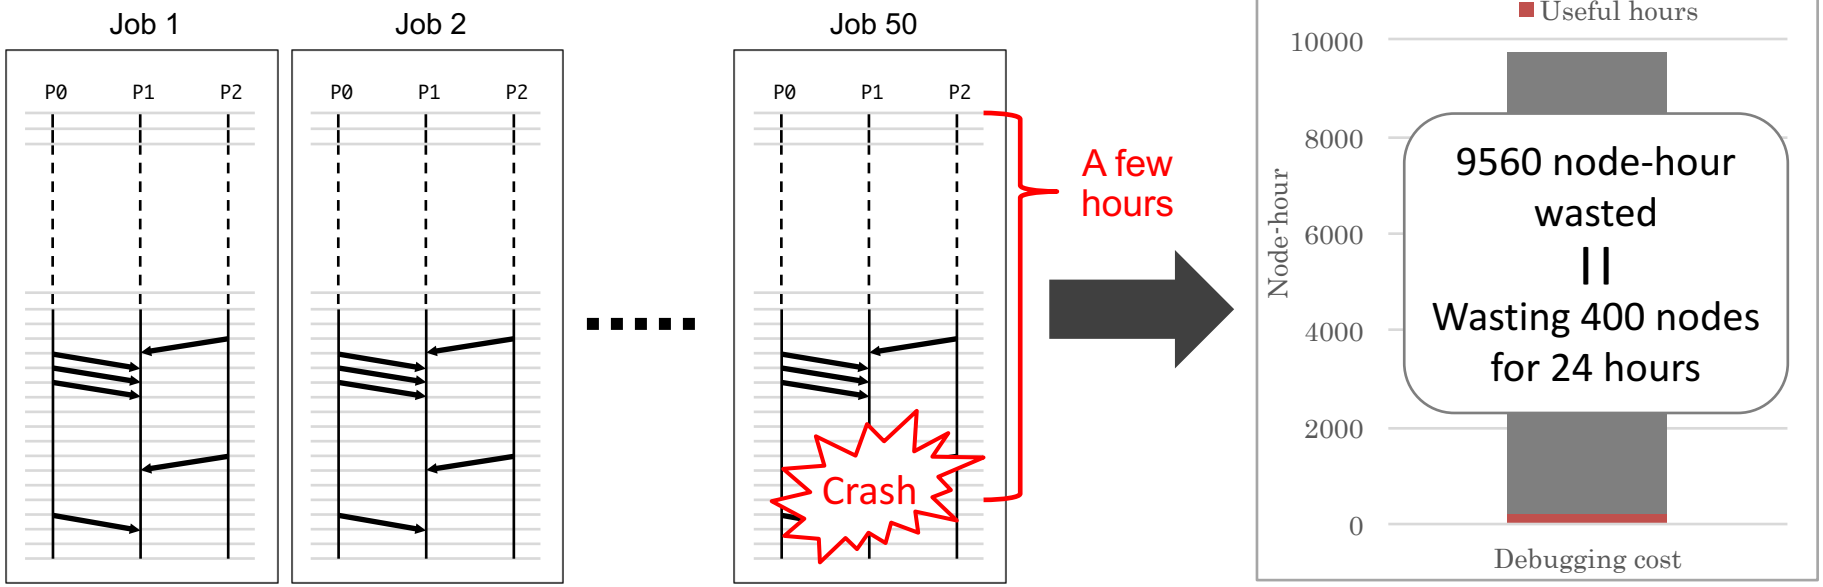
Observing a non-deterministic bug is costly

- MPI non-deterministic bugs do not frequently manifest
  - In the Diablo/Hypre 2.10.1 case, the bug manifests
    - Only one out of 50 jobs (i.e. 2% of jobs)
    - After a few hours
- We need to submit a bunch of debug jobs to observe the bug (wasting resources)
- Rarely occurring message race bugs waste both scientists' productivity and machine resources (thereby affect other users)



A tool to frequently and quickly expose message race bugs is invaluable
